**Background:** In this study the correlation between dyspnoea and load on the ventilatory muscles was assessed. Both inspiratory and expiratory muscle load were of our interest. This was done in patients with obstructive pulmonary diseases during an incremental maximal exercise test. A subdivision was made between patients with or without a ventilatory exercise limitation. The first was defined as an increase in  $P_aCO_2$  during exercise.

**Methods:** Fifty patients with a wide range of obstructive pulmonary diseases ( $FEV_1$  %pred.:  $66.1 \pm 28.8$ ) performed an incremental cycle ergometer test. During the test dyspnoea (Borg), oesophageal pressures, mechanical load on the ventilatory muscles (time tension index (TTI)) and minute ventilation were measured. The amplitude of pleural pressures ( $P_i + P_e$ )<sub>act</sub> generated at  $W_{max}$  was multiplied with the breathing frequency (PFP, indication of the muscle load).  $PFP\%$  was calculated from: frequency  $\times (P_{i\ act} + P_{e\ act}) / (P_{i\ max} + P_{e\ max})$ . Linear regression between  $V_E$  and PFP at  $W_{max}$  was calculated for both groups. The slopes of these relationships give an impression of the length-tension-inappropriateness. When there was a difference in slope it was assessed whether this led to a difference in Borg score for dyspnoea between the two groups. Correlations between the changes in  $TTI_i$ ,  $TTI_e$ , PFP,  $PFP\%$  and Borg dyspnoea for both groups were calculated.

**Results:** The slope of  $V_E/PFP$  of the non ventilatory limited group was 0.17 l/kPa ( $P = 0.007$ ). The slope of  $V_E/PFP$  for the ventilatory limited group was 0.01 L/kPa ( $P = 0.7$ ). The difference between the slopes (0.16) was highly significant (CI(0.159–0.161)). However there was no difference between the Borg score for dyspnoea between those groups (mean Borg vent. lim.:  $5.9 \pm 2.6$ ; mean Borg not vent. lim.:  $5.9 \pm 2.1$ ;  $P = 0.945$ ). The change in  $TTI_i$  was  $0.04 \pm 0.05$  for the ventilatory limited group and  $0.07 \pm 0.07$  for the non ventilatory limited group, which was not significant. The change in  $TTI_e$  was  $0.08 \pm 0.08$  and  $0.06 \pm 0.07$  for the ventilatory and the non ventilatory limited group respectively and was also not significant.

Table 1. Correlations ( $r$ ) between Borg dyspnoea (Bd) and  $TTI_i$ ,  $TTI_e$ , PFP and  $PFP\%$ , none of the correlations were significant

	Bd			
	$TTI_i$	$TTI_e$	PFP	$PFP\%$
Total ( $N = 50$ )	$r = -0.2272$	$r = 0.0614$	$r = 0.1507$	$r = -0.0013$
Vent. lim. ( $N = 22$ )	$r = -0.1467$	$r = 0.0652$	$r = 0.1922$	$r = 0.1741$
Nvent. lim. ( $N = 28$ )	$r = -0.3143$	$r = 0.0619$	$r = 0.1124$	$r = -0.1396$

*Conclusions:* The sensation of dyspnoea during exercise in patients with obstructive lung disease, did not correlate with parameters of length tension inappropriateness in respiratory muscles. Other parameters of ventilatory muscle load did also not correlate with Borg score for dyspnoea.
